

Municipal Satisfaction Benchmark Dashboard

Power BI dashboard for satisfaction benchmarking, demographic representativeness, and improvement-priority analysis

Built a solo Power BI case study using municipal citizen satisfaction survey data from a municipal citizen satisfaction survey. The report helped users explore public sentiment across Canadian municipal issues, compare weighted and unweighted views, inspect demographic composition against StatsCan benchmarks, and identify service areas requiring follow-up analysis.

The dashboard was designed as a guided reporting experience: from national overview, to municipal factor diagnostics, to demographic representativeness, recovery priorities, and exploratory correlation analysis.

Quick facts

Project: Solo academic dashboard

Survey scope: Canada benchmark

Respondents: 2,730

Weighting: Age, gender, province

Tools: Power BI, DAX, Power Query

Power BI

DAX

Power Query

Weighted reporting

Survey benchmarking

Business problem

The project request was to create a high-level dashboard that helped a client understand public sentiment on key municipal issues and assess whether the survey sample was representative compared with StatsCan Census data. The dashboard needed to support both presentation storytelling and self-serve exploration rather than only static summary tables.

Dashboard overview

- Multi-page Power BI report covering overview, municipal factors, demographics, recovery priorities, correlation analysis, and StatsCan comparison.
- Weighted and unweighted views, where weighting adjusted age, gender, and province distribution against StatsCan benchmark data.
- Interactive navigation and filters for province and demographic cuts, allowing users to move from top-line results into diagnostic views.

Overview page: respondent count, weighted/unweighted toggle, provincial distribution, quality-of-life ratings, map view, and municipal recommendation trend.

From reporting to diagnosis

Analysis design

The dashboard was structured to move from overview to diagnosis: municipal factor ratings identified satisfaction patterns, recovery views ranked lower-rated service areas for follow-up, correlation views explored relationships between coded questionnaire variables, and the StatsCan page made sample composition visible.

Recovery and correlation views: lower-rated services were treated as higher-priority areas for follow-up; correlation was exploratory, not causal.

Key interpretation

- Overall satisfaction appeared moderate, with public safety and quality of life more positive than several service/cost areas.
- Housing, tax value, and selected public services stood out as weaker areas requiring follow-up analysis.

Correlation / NPS

- All municipalities showed negative NPS in the available dashboard view.
- Taxation (T1), municipal service satisfaction (SA3), and municipal recommendation (SA1) showed stronger relationships than demographic variables.

Recovery logic

- Lower satisfaction ratings were used to prioritize service areas for recovery analysis.
- Children's services, social assistance services, and housing services were treated as higher-priority candidates.

Limitations

- Academic project with a limited dataset representing Canada.
- Correlation is exploratory and should not be read as causation; coded variables need clearer production documentation.

Portfolio value

This project is supporting evidence of Power BI dashboard design, survey benchmark reporting, demographic profiling, weighted reporting, and analytical storytelling. It shows how I translate a broad research request into an interactive reporting tool that helps stakeholders understand sample context, compare municipal satisfaction patterns, and identify areas for further investigation.

StatsCan comparison view: survey distribution versus external demographic benchmark data.
